Surveillance data on *Clostridium difficile* associated diarrhea in Québec hospitals

The surveillance system for diarrhea associated with the bacterium *Clostridium difficile*, generally called *C. difficile*, was introduced in Québec's hospitals in August 2004. It is overseen by the Institut national de santé publique du Québec (INSPQ).

Nearly 100 hospitals throughout Québec monitor the incidence of these nosocomial infections. Most institutions have more than 1,000 admissions for short-term care annually, excluding psychiatry, nursery and neonatology units.

The main objective of the surveillance system is to track trends in rates in the province's hospitals so that appropriate control measures can be adopted.

The purpose of this document is to inform the public about the presence of nosocomial *Clostridium difficile* infections by presenting the incidence rates by hospital, by health region, and for all of Québec. Rates are calculated using validated data to ensure accuracy. The validation procedure involves a number of steps and takes three months after the end of each administrative period.

WARNING

It is important to remember to **be cautious when interpreting data on the incidence of *Clostridium difficile***-associated diarrhea in hospitals, especially when comparing institutions and regions. A number of factors can influence the rates: the size of the institution, the complexity of the services offered, the type of population served, the physical layout of the facilities, the number of people hospitalized for respiratory infection, the use of antibiotics, the percentage of people aged 65 and over and, of course, the virulence and transmissibility of the circulating strain of the bacterium.

Clostridium difficile-associated diarrhea rates vary seasonally and usually increase over the winter months. Rates can also fluctuate widely from one period to the next in small institutions. A single case of infection can result in a high rate for a small hospital.

To clearly understand the meaning of these data, readers may consult the detailed epidemiological reports produced by the INSPQ and posted on the Institute's Web site at www.inspq.qc.ca.

Presentation of data on *Clostridium difficile*

Surveillance data on *Clostridium difficile*-associated diarrhea refer to hospital-acquired infections, i.e., infections whose symptoms began more than 72 hours after admission to hospital or less than four weeks after the patient's discharge.

Data are presented in tabular and graph formats for each of Québec's health regions, excluding Nunavik (region 17) and Terres-Cries-de-la-Baie-James (region 18). The **tables** show the incidence rates for each participating hospital and each administrative period. The incidence rate is calculated by dividing the number of new cases observed by the number of patient days; patient days represent the number of patients hospitalized (beds occupied) in the institution during a given administrative period. For example, if for a 10-day period, the cumulative number of bed occupancy days for the entire institution is 1,000, we obtain 10,000 patient days. This unit of measurement allows the level of hospital activity (bed occupancy), which fluctuates over time and differs from hospital to hospital, to be taken into account. Rates therefore express the number of cases per 10,000 patient days. Data are usually aggregated

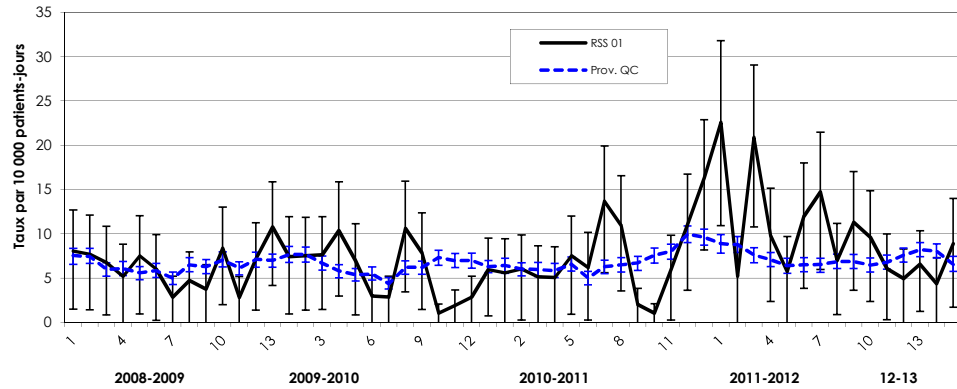

(grouped) by four-week administrative period. There are 13 periods per year. Hospital size is expressed as the number of beds, and the percentage of patients over 65 years of age is indicated.

Each regional incidence rate is presented **graphically** and is compared to the provincial incidence rate. Regional incidence rates are calculated from the data provided by the hospitals in a given region. Regional groupings are created based on shared characteristics. Lastly, provincial rates, encompassing data from all participating hospitals, are also calculated.
